Definition of Limits

Definition 3.1

Let $f: \mathbb{R} \to \mathbb{R}$ and let $a, L \in \mathbb{R}$. We say that

$$\lim_{x \to a} f(x) = L$$

if, for every $\varepsilon > 0$, there exists a $\delta > 0$ such that

$$0 < |x - a| < \delta \implies |f(x) - L| < \varepsilon.$$

Consider

$$f(x) = \begin{cases} \frac{2x^2 - x - 1}{x - 1}, & x \neq 1, \\ 0, & x = 1. \end{cases}$$

- Simplify f(x) for $x \neq 1$. f(x) = ?
- From (a), the limit

$$L = \lim_{x \to 1} f(x) = ?$$

- Starting from the goal inequality $|f(x) L| < \varepsilon$ for various $\varepsilon > 0$, derive an *equivalent inequality* for |x 1|. Hence, find a suitable δ in each case.
- What happens at x = 1? Obviously, |f(1) L| = |0 L| > 0.1. Does this violate the statement $\lim_{x \to 1} f(x) = L$?

Excercise 1(a)(b): Solutions

Simplify the numerator:

$$2x^2 - x - 1 = (2x+1)(x-1).$$

Thus, for $x \neq 1$,

$$f(x) = \frac{2x^2 - x - 1}{x - 1} = \frac{(2x + 1)(x - 1)}{x - 1} = 2x + 1.$$

$$f(x) = 2x + 1 \quad (x \neq 1)$$

• From part (a),

$$L = \lim_{x \to 1} f(x) = \lim_{x \to 1} (2x + 1) = 2(1) + 1 = 3.$$

$$L=3$$

Excercise 1(c)

By the definition of limits, we are claiming that:

We can make f(x) arbitrarily close to L by restricting x to be sufficiently close to 1 but not equal to 1.

To justify the above claim, we need to show that, for each (small) positive number ε , there is a positive number δ (which may depend on ε) such that $0 < |x-1| < \delta$ implies $|f(x) - L| < \varepsilon$.

Exercise 1(c): Solutions

($\varepsilon = 0.1$)

$$|f(x) - L| < 0.1 \iff |2(x+1) - 3| < 0.1 \iff |x - 1| < 0.05.$$

Therefore, we can pick $\delta = 0.05$, which satisfies

$$0 < |x - 1| < 0.05 \implies |f(x) - L| < 0.1$$

 $(\varepsilon = 0.01)$

$$|f(x) - L| < 0.01 \iff 2|x - 1| < 0.01 \iff |x - 1| < 0.005.$$

Therefore, we can pick $\delta = 0.005$, which satisfies

$$0 < |x - 1| < 0.005 \implies |f(x) - L| < 0.01$$

Exercise 1(c): Solutions

(General case)

$$|f(x) - L| < \varepsilon \iff 2|x - 1| < \varepsilon \iff |x - 1| < \frac{\varepsilon}{2}.$$

Therefore, we can pick $\delta = \frac{\varepsilon}{2}$, which satisfies

$$0 < |x - 1| < \frac{\varepsilon}{2} \implies |f(x) - L| < \varepsilon$$

Excercise 1(d): Solutions

What happens at x = 1? Obviously, |f(1) - L| = |0 - L| > 0.1. Does this violate the statement $\lim_{x \to 1} f(x) = L$?

No. Recall the definition of limit,

... such that
$$0 < |x - a| < \delta \implies |f(x) - L| < \varepsilon$$
.

That is, we don't care about the case |x-1|=0 in the definition of limit. Thus, it does not violate the statement $\lim_{x\to 1} f(x) = L$.

Our goal is to show, by using the precise definition, that

$$\lim_{x \to 0} \sqrt[3]{x} = 0.$$

- Write down the precise definition of $\lim_{x\to 0} \sqrt[3]{x} = 0$.
- We now attempt to verify the precise definition.
 - ① Starting from the 'goal inequality' $|\sqrt[3]{x} 0| < \varepsilon$, derive an equivalent inequality for |x 0|.
 - 1 Hence, for each $\varepsilon > 0$, find δ and complete the proof of $\lim_{x \to 0} \sqrt[3]{x} = 0$.

Exercise 2(a): Solutions

By the definition of limit:

For all $\varepsilon > 0$, there is $\delta > 0$ such that

$$0 < |x - 0| < \delta$$
 implies $|\sqrt[3]{x} - 0| < \varepsilon$.

This is the precise definition of $\lim_{x\to 0} \sqrt[3]{x} = 0$.

Exercise 2(b): Solutions

① Start from the goal inequality:

$$|\sqrt[3]{x} - 0| < \varepsilon.$$

This is equivalent to

$$|\sqrt[3]{x}| < \varepsilon$$
.

Cubing both sides (since cube is monotone increasing):

$$|x| < \varepsilon^3$$
.

• From part (i), the condition becomes:

$$|x| < \varepsilon^3$$
.

Therefore, for each $\varepsilon > 0$, we can choose

$$\delta = \varepsilon^3$$
.

Then, whenever $0 < |x| < \delta$, we have

$$|\sqrt[3]{x} - 0| < \varepsilon.$$

By imitating the precise definition of a limit, write down precise definitions of one-sided limits.

$$\lim_{x \to a^+} f(x) = L$$

$$\lim_{x \to a^{-}} f(x) = L$$

Exercise 3: Solutions

 \bullet $\lim_{x\to a^+} f(x) = L$ means: For every $\varepsilon > 0$, there exists $\delta > 0$ such that

$$0 < x - a < \delta \implies |f(x) - L| < \varepsilon.$$

② $\lim_{x\to a^-} f(x) = L$ means: For every $\varepsilon > 0$, there exists $\delta > 0$ such that

$$0 < a - x < \delta \implies |f(x) - L| < \varepsilon.$$

Definition of Infinite Limits

Definition 3.2

Let $f: \mathbb{R} \to \mathbb{R}$ and let $a \in \mathbb{R}$. We say that

$$\lim_{x \to a} f(x) = +\infty$$

if, for every M > 0, there exists a $\delta > 0$ such that

$$0 < |x - a| < \delta \implies f(x) > M.$$

Similarly,

$$\lim_{x \to a} f(x) = -\infty$$

if, for every N < 0, there exists a $\delta > 0$ such that

$$0 < |x - a| < \delta \implies f(x) < N.$$

Imitating the above definition, write down precise definitions of other limits regarding infinity:

$$\lim_{x \to a^{-}} f(x) = -\infty$$

$$\lim_{x \to \infty} f(x) = L$$

$$\lim_{x \to -\infty} f(x) = \infty$$

Exercise 4: Solutions

 $\lim_{x\to a^-} f(x) = -\infty \text{ means: For every } N<0, \text{ there exists a } \delta>0$ such that

$$0 < a - x < \delta \implies f(x) < N.$$

 $\lim_{x\to\infty} f(x) = L$ means: For every $\varepsilon > 0$, there exists M > 0 such that

$$x > M \implies |f(x) - L| < \varepsilon.$$

 $\lim_{\substack{x\to -\infty\\\text{that}}} f(x) = \infty \text{ means: For every } K>0, \text{ there exists } M<0 \text{ such that}$

$$x < M \implies f(x) > K.$$

Our goal is to show, by using the precise definition, that

$$\lim_{x \to 0^+} \ln x = -\infty.$$

- Write down the precise definition of ' $\lim_{x\to 0^+} \ln x = -\infty$ '.
- We now attempt to verify the precise definition.
 - ① Firstly, starting from the 'goal inequality' $\ln x < N$, derive an inequality for x 0.

Exercise 5: Solutions

• Precise definition: $\lim_{x\to 0^+} \ln x = -\infty$ means: For every N<0, there exists $\delta>0$ such that

$$0 < x < \delta \implies \ln x < N.$$

- Verification:
 - \bigcirc Starting from $\ln x < N$, we exponentiate to obtain

$$x < e^N$$
.

So the condition becomes $0 < x < e^N$.

• For a given N < 0, set $\delta = e^N > 0$. Then for all x with $0 < x < \delta$, we have

$$\ln x < N$$
.

Hence, by the precise definition,

$$\lim_{x \to 0^+} \ln x = -\infty.$$

Consider a function f which is defined for x > 0.

- Prove that if f(x) > 0 for all x > 0 and the limit $\lim_{x \to \infty} f(x) = L$ exists, then $L \ge 0$. (Hint. Argue by contradiction.)
- Deduce that if f(x) > g(x) for all x > 0 and the limits $\lim_{x \to \infty} f(x) = L$ and $\lim_{x \to \infty} g(x) = M$ exist, then $L \ge M$.

Exercise 6: Solutions

Suppose L < 0. Since $\lim_{x \to \infty} f(x) = L$, there exists M > 0 such that

$$x > M \Longrightarrow |f(x) - L| < \varepsilon = -L.$$

Then, we obtain

$$|f(x) - L| < -L \Longrightarrow f(x) < 0.$$

This contradicts to f(x) > 0 for all x > 0. Thus, $L \ge 0$

• Let h(x) = f(x) - g(x). Since f(x) > g(x) for all x > 0, h(x) > 0 for all x > 0. Also,

$$\lim_{x \to \infty} h(x) = \lim_{x \to \infty} [f(x) - g(x)] = L - M \quad \text{exists (by 7(a))}$$

By 6(a),
$$L - M \ge 0 \Longrightarrow L \ge M$$

Consider a function f(x) which is defined around x = a. Prove the following statements.

- Prove that if $\lim_{x\to a} f(x) = L$ and $\lim_{x\to a} g(x) = M$ then $\lim_{x\to a} [f(x) + g(x)] = L + M$.
- Prove that if $\lim_{x\to a} f(x) = 0$ and |g(x)| < M for all x where M > 0 is a constant then $\lim_{x\to a} f(x)g(x) = 0$
- Prove that if $\lim_{x\to a} f(x) = L > 0$ and $\lim_{x\to a} g(x) = \infty$ then $\lim_{x\to a} f(x)g(x) = \infty$

Exercise 7(a): Solutions

• Since $\lim_{x\to a} f(x) = L$ and $\lim_{x\to a} g(x) = M$, for every $\varepsilon > 0$ there exist $\delta_1, \delta_2 > 0$ such that

$$|f(x) - L| < \frac{\varepsilon}{2}, \quad |g(x) - M| < \frac{\varepsilon}{2}$$

whenever $0 < |x - a| < \delta = \min(\delta_1, \delta_2)$. Then

$$|(f(x) + g(x)) - (L + M)| \le |f(x) - L| + |g(x) - M| < \varepsilon.$$

Hence, $\lim_{x \to a} [f(x) + g(x)] = L + M$.

Exercise 7(b): Solutions

• Given $\lim_{x\to a} f(x) = 0$, for any $\varepsilon > 0$ there exists $\delta > 0$ such that

$$|f(x)| < \frac{\varepsilon}{M}$$
 whenever $0 < |x - a| < \delta$.

Since |g(x)| < M, we have

$$|f(x)g(x)| \le |f(x)| \cdot |g(x)| < \frac{\varepsilon}{M} \cdot M = \varepsilon.$$

Thus $\lim_{x \to a} f(x)g(x) = 0$.

Exercise 7(c): Solutions

Then for $\varepsilon = L/2 > 0$, there exists $\delta_1 > 0$ such that $|f(x) - L| < L/2 \Rightarrow f(x) > \frac{L}{2}$ when $0 < |x - a| < \delta_1$.

Since $\lim_{x\to a} g(x) = \infty$, for any N > 0, there exists $\delta_2 > 0$ such that $g(x) > \frac{2N}{L}$ whenever $0 < |x-a| < \delta_2$.

Thus, for $\delta = \min(\delta_1, \delta_2)$ we have

$$f(x)g(x) > \frac{L}{2} \cdot \frac{2N}{L} = N.$$

Since N is arbitrary, $\lim_{x\to a} f(x)g(x) = \infty$.
